Modeling Materials Properties and Functions: The Many-Body Schrödinger Equation

$$\begin{split} (\hat{T}^e + \hat{T}^{ion} + \hat{V}^{e-e} + \hat{V}^{e-ion} + \hat{V}^{ion-ion})\Psi &= E\Psi \\ \text{With:} \quad \Psi(\mathbf{r_1}, \cdots \mathbf{r_N}; \mathbf{R_1}, \cdots \mathbf{R_M}) \\ \hat{T}^e &= \sum_{k=1}^N \frac{\mathbf{p}_k^2}{2m} \qquad \hat{T}^{ion} = \sum_{I=1}^M \frac{\mathbf{P}_I^2}{2M_I} \\ \hat{V}^{e-e} &= \frac{1}{2} \frac{1}{4\pi\epsilon_0} \sum_{k \neq k'}^{N,N} \frac{e^2}{|\mathbf{r_k} - \mathbf{r_{k'}}|} \\ \hat{V}^{ion-ion} &= \frac{1}{2} \frac{1}{4\pi\epsilon_0} \sum_{I \neq I'}^{M,M} \frac{Z_I Z_{I'}}{|\mathbf{R_I} - \mathbf{R_{I'}}|} \\ \hat{V}^{e-ion}(\mathbf{r_k}, \mathbf{R_I}) &= \sum_{k=1}^N \sum_{I=1}^M \mathbf{v_I^{ion}}(|\mathbf{R_I} - \mathbf{r_k}|) \end{split}$$

Modeling Materials Properties and Functions: The Many-Body Schrödinger Equation

$$(\hat{T}^{e} + \hat{T}^{ion} + \hat{V}^{e-e} + \hat{V}^{e-ion} + \hat{V}^{ion-ion})\Psi = E\Psi$$
With:
$$\Psi(\mathbf{r_{1}}, \cdots \mathbf{r_{N}}; \mathbf{R_{1}}, \cdots \mathbf{R_{M}})$$

$$\hat{T}^{e} = \sum_{k=1}^{N} \frac{\mathbf{p}_{k}^{2}}{2m} \qquad \hat{T}^{ion} = \sum_{I=1}^{M} \frac{\mathbf{p}_{I}^{2}}{2M_{I}}$$

$$\hat{V}^{e-e} = \frac{1}{24\pi\epsilon_{0}} \sum_{j\neq l'}^{NN} \frac{e^{2}}{|\mathbf{r_{k}} - \mathbf{r_{k'}}|} \qquad \text{We know the operators and the interactions. We can write them down.}$$

$$\hat{V}^{e-ion}(\mathbf{r_{k}}, \mathbf{R_{I}}) = \sum_{k=1}^{N} \sum_{I=1}^{M} \mathbf{v_{I}^{ion}}(|\mathbf{R_{I}} - \mathbf{N_{k'}}|) \qquad \mathbf{v_{I}^{ion}}(|\mathbf{R_{I}} - \mathbf{V_{k'}}|) \qquad \mathbf{v_{I}^$$

Born-Oppenheimer Approximation

$$\Psi(\mathbf{r}_1,\cdots\mathbf{r}_N;\mathbf{R}_1,\cdots\mathbf{R}_M) = \sum_{\nu} \Lambda_{\nu}(\{\mathbf{R}_I\}) \Phi_{\nu} \, _{\{\mathbf{R}_I\}}(\{\mathbf{r}_k\})$$

Where Φ_{ν} are solutions of the "electronic Hamiltonian":

$$H_{\{\mathbf{R}_{\mathbf{I}}\}}^{e} \Phi_{\nu, \{\mathbf{R}_{\mathbf{I}}\}}(\{\mathbf{r}_{\mathbf{k}}\}) = E_{\nu, \{\mathbf{R}_{\mathbf{I}}\}}^{e} \Phi_{\nu, \{\mathbf{R}_{\mathbf{I}}\}}(\{\mathbf{r}_{\mathbf{k}}\})$$

$$H^{e} = T^{e} + V^{e-e} + V^{e-ion}$$

frequently (commonly) applied approximations:

- neglect non-adiabatic coupling (terms of order m/M_I)
- keep only Λ_0
- the dynamics of electrons and nuclei decouple

Some Limits of the Born-Oppenheimer Approximation

It does not account for correlated dynamics of ions and electrons. For example:

- polaron-induced superconductivity
- dynamical Jahn-Teller effect at defects in crystals
- some phenomena of diffusion in solids
- non-adiabaticity in molecule-surface scattering and chemical reactions
- relaxation and transport of charge carriers $(e^- \text{ or } h)$
- etc.

Some Limits of the Born-Oppenheimer Approximation

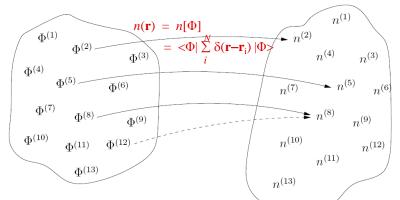

It does not account for correlated dynamics of ions and electrons. For example:

These limits can be severe. Nevertheless, we will use the BO approximation in the following.

How can we solve:

$$H^e_{\{\mathbf{R_I}\}}\Phi_{
u,\{\mathbf{R_I}\}}(\mathbf{r_k}) = E^e_{
u,\{\mathbf{R_I}\}}\Phi_{
u,\{\mathbf{R_I}\}}(\mathbf{r_k})$$
 is $H^e = T^e + V^{e-e} + V^{e-ion}$

The Hohenberg-Kohn Theorem (1964)

Set of non-degenerate ground-state wave functions Φ of arbitrary N-electron Hamiltonians.

Set of particle densities $n(\mathbf{r})$ belonging to non-degenerate N-electron ground states.

The dashed arrow is not possible. Thus, here is a one-to-one correspondence between Φ and n(r).

Density Functional Theory

The energy of the ground state of a many-electron system : $E_0\left(\{\mathbf{R}_I\}\right) = \mathrm{Min}_\Phi <\Phi |H^e|\Phi>$

Hohenberg and Kohn (1964): The functional

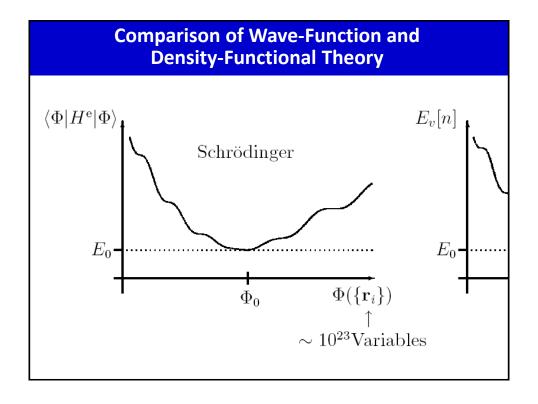

$$n(\mathbf{r}) = n[\Phi] = \langle \Phi | \sum_{i} \delta(\mathbf{r} - \mathbf{r}_{i}) | \Phi \rangle$$

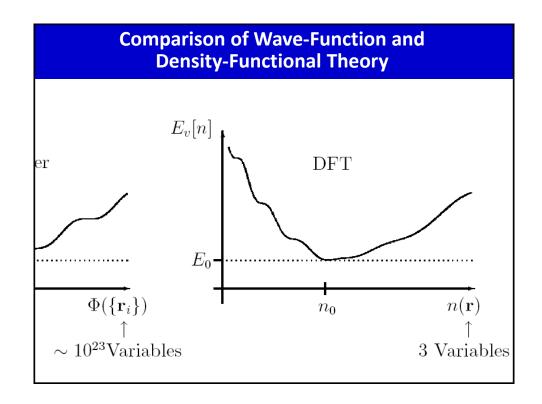

can be inverted, i.e.,

$$\Phi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_N) = \Phi[n(\mathbf{r})]$$
.

This implies:

$$E_0\left(\left\{\mathbf{R}_I\right\}\right) = \operatorname{Min}_{n(\mathbf{r})} E_{\left\{\mathbf{R}\right\}}\left[n\right]$$

Summary of Hohenberg-Kohn Density-Functional Theory (DFT) -- 1964

- -- The many-body Hamiltonian determines everything. (standard quantum mechanics)
- -- There is a one-to-one correspondence between the ground-state wave function and the many-body Hamiltonian [or the nuclear (or ionic) potential, v(r)]. (standard quantum mechanics)
- -- There is a one-td-one correspondence between the ground-state electron-density and the ground-state wave function. (Hohenberg and Kohn)

Kohn and Sham (1965):

$$E_v[n] = T_s[n] + \int v(\mathbf{r}) n(\mathbf{r}) d^3 \mathbf{r} + E^{\text{Hartree}}[n] + E^{\text{xc}}[n]$$
with
$$E^{\text{Hartree}}[n] = \frac{1}{2} \frac{e^2}{4\pi\varepsilon_0} \iint \frac{n(\mathbf{r}) n(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3 \mathbf{r} d^3 \mathbf{r}'$$

And $T_s[n]$ the functional of the kinetic energy of **noninteracting** electrons. $E^{xc}[n]$ contains all the unknowns.

At fixed electron number N the variational principle gives

$$\delta \left\{ E_v[n] - \mu \left(\int n(\mathbf{r}) d^3 \mathbf{r} - N \right) \right\} = 0$$
or
$$\frac{\delta E_v^{[n]}}{\delta n} = \mu = \frac{\delta T_s[n]}{\delta n(\mathbf{r})} + v^{\text{eff}}(\mathbf{r})$$
Rohn-Sham equation

Kohn and Sham (1965):

$$v^{\text{eff}}(\mathbf{r}) = v(\mathbf{r}) + \frac{e^2}{4\pi\varepsilon_0} \int \frac{n(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3\mathbf{r}' + \frac{\delta E^{\text{xc}}[n]}{\delta n(\mathbf{r})}$$

Because $T_s[n]$ is the functional of non-interacting particles we effectively restrict the allowed densities to those that can be written as

This implies:

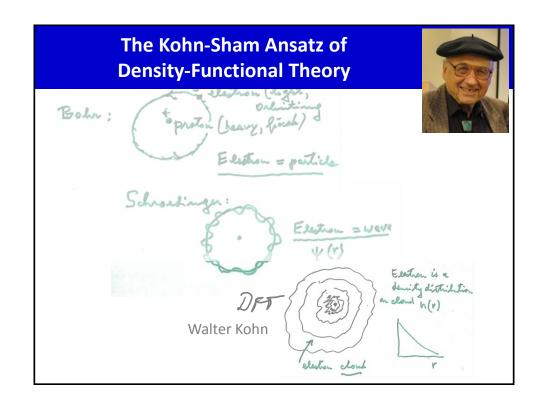

$$n(\mathbf{r}) = \sum_{i=1}^{N} |\varphi_i(\mathbf{r})|^2$$
Kohn-Sham

$$\left\{-\frac{\hbar^2}{2m}\nabla^2+v^{\rm eff}(\mathbf{r})\right\}\varphi_i\left(\mathbf{r}\right)=\epsilon_i^{}\varphi_i^{}\left(\mathbf{r}\right) \qquad \text{equation}$$

 $v^{\text{eff}}(\mathbf{r})$ depends on the density that we are seeking.

$$T_{s}[n] = \sum_{k=1}^{N} \langle \varphi_{k} | -\frac{\hbar^{2}}{2m} \nabla^{2} | \varphi_{k} \rangle ,$$

$$= \sum_{k=1}^{N} \epsilon_{k} - \int v^{\text{eff}}[n^{\text{in}}](\mathbf{r}) n(\mathbf{r}) d^{3}\mathbf{r}$$

The Kohn-Sham Ansatz of Density-Functional Theory

 Kohn-Sham (1965): Replace the original many-body problem by an independent electron problem that can be solved!

$$E_{v}[n] = T_{s}[n] + \int v(\mathbf{r}) n(\mathbf{r}) d^{3}\mathbf{r} + E^{\text{Hartree}}[n] + E^{xc}[n]$$

- With $T_{\rm s}$ [n] the kinetic energy functional of independent electrons, and $E^{\rm xc}[n]$ the unknown functional.
- The challenge is to find useful, approximate xc functionals.

The Kohn-Sham Ansatz of Density-Functional Theory

Approximate xc functionals have been very successful but there are problems

- for certain bonding situations (vdW, hydrogen bonding, certain covalent bonds)
- for highly correlated situations, and
- for excited states.
- The challenge is to find useful, approximate xc functionals.

Certainties about Density Functional Theory

- 1. DFT in principle: It is exact; a universal $E^{xc}[n]$ functional "exists".
- 2. DFT in practice: It is probably not possible to write down $E^{\text{xc}}[n]$ as a closed mathematical expression. We need approximations.

The success of DFT proves that "simple" approximations to the exchange-correlation functional can provide good results – if one knows what one is doing.

Certainties about Density Functional

- 1. DFT in principle: It is exact; a unix $E^{xc}[n]$ functional "exists".
- ot possible to write 2. DFT in practice: It is prob Mematical expression. down $E^{xc}[n]$ as a close We need approximate

The success of Diversity over that "simple" approximations to the exchange relation functional can provide good nows what one is doing.

Some remarks about excited states

What About the Kohn-Sham Eigenvalues?

The only quantities that are supposed to be correct in the Kohn-Sham approach are electron density, total energy, highest Kohn-Sham level, forces, force constants, ...

What about the individual $\varphi_i(\mathbf{r})$ and ε_i ?

The Kohn-Sham $\varphi_i(\mathbf{r})$ and ε_i give an approximate description of quasi-particles, a (good) starting point for many-body calculations.

Kohn-Sham eigenvalues are not excitation energies.

However, $\varphi_i(\mathbf{r})$ and ε_i give an approximate description of quasi-particles, a (good) **starting point** for many-body calculations.

What About Kohn-Sham Eigenvalues?

The ionization energy is:

$$I_k = E_k^{N-1} - E^N$$

$$n(\mathbf{r}) = \sum_{i=1}^{\infty} f_i |\varphi_i(\mathbf{r})|^2$$

 f_i are occupation numbers

$$= -\int_0^1 \frac{\partial E_v[n]}{\partial f_k} df_k$$

(Well defined for the highest occupied state. Otherwise, "only" in terms of constrained DFT)

$$= -\int_0^1 \epsilon_k(f_k) \, df_k$$

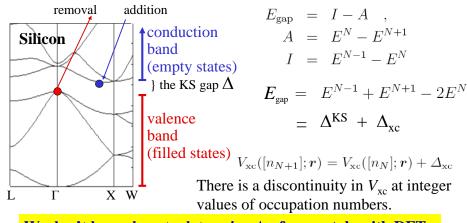

Here we assume that the positions of the atoms don't change upon ionization, or that they change with some delay (Franck-Condon principle). Using the mean-value theorem of integral algebra gives: $I_k = -\epsilon_k(0.5)$

This is the Slater-Janak "transition state". It is the DFT analog of Koopmans' theorem.

Kohn-Sham Electron Bands

Kohn-Sham band gap: $\Delta^{\text{KS}} = \epsilon_{\text{CB}} - \epsilon_{\text{VB}}$ of the *N*-particle system

The measured (optical) band gap is something else:

We don't know how to determine Δ_{xc} for crystals with DFT.

Summary and Outlook: Interacting Electrons Determine the Properties and Function of Real Materials

Important arenas for future theoretical work:

- Non-adiabatic effects, dissipation
- Transport (electrons, ions, heat)
- Thermodynamic phase transitions, e.g. melting
- Surfaces, nanostructures in realistic environments
- Modeling the kinetics, e.g. of catalysts or crystal growth (self-assembly and self-organization)
- Molecules and clusters in solvents, electrochemistry, fuel cells, external fields
- Correlated systems, e.g. f-electron chemistry
- Biological problems

The challenges:

- Find ways to control the xc approximation
- Develop methods for bridging length and time scales
